Colon Polyps

Anne Charette, RN, MSN, ANP; Robert H. Fletcher, MD, MSC; J. Thomas LaMont, MD; Leah K. Moynihan, RNC, MSN; Peter A. L. Bonis, MD.

Colorectal cancer is uncommon before age 40. Ninety percent of cases occur after age 50, with men and women being similarly affected; therefore, colon cancer screening is usually recommended starting at age 50 for both sexes. It takes approximately 10 years for a small polyp to develop into cancer. Polyps are very common in men and women of all races who live in industrialized countries, which suggests that dietary and environmental factors play a role in their development.

What causes Colon Polyps?

Polyps are very common in men and women of all races who live in industrialized countries, which suggests that dietary and environmental factors play a role in their development.

Lifestyle

Although the exact causes are not completely understood, lifestyle risk factors include the following:

- A high fat diet
- Cigarette smoking
- Obesity

On the other hand, use of aspirin and other NSAIDs and a high calcium diet may protect against the development of colon polyps. Another, Hereditary Non-Polyposis Colon Cancer (HNPCC), increases the risk of colon cancer, often beginning in the 20s and 30s, but does not cause a large number of polyps. Testing for these genes may be recommended for families with high rates of colorectal cancer, but is not generally recommended for other groups.

Aging

Colorectal cancer is uncommon before age 40. Ninety percent of cases occur after age 50, with men and women being similarly affected; therefore, colon cancer screening is usually recommended starting at age 50 for both sexes. It takes approximately 10 years for a small polyp to develop into cancer.

Types of Colon Polyps

adenomatous polyps. Other types of polyps can also be found in the colon, although these are far less common and not discussed here.
Hyperplastic polyps

Hyperplastic polyps are usually small, located in the end-portion of the colon (the rectum and sigmoid colon), have no potential to become malignant, and are not worrisome. It is not always possible to distinguish a hyperplastic polyp from an adenomatous polyp based upon appearance during colonoscopy, which means that hyperplastic polyps are often removed or biopsied to allow microscopic examination.

Adenomatous polyps

Two-thirds of colon polyps are adenomas. Most of these polyps do not develop into cancer, although they have the potential to become cancerous. Adenomas are classified by their size, general appearance, and their specific features as seen under the microscope.

As a general rule, the larger the adenoma, the more likely it is to eventually become a cancer. As a result, large polyps are usually biopsied (a small sample of tissue is removed) or removed completely to allow for microscopic examination.

Malignant polyps

Polyps that contain pre-cancerous or cancerous cells are known as malignant polyps. The optimal treatment for malignant polyps is to eventually become a cancer. As a result, large polyps are usually biopsied (a small sample of tissue is removed) or removed completely to allow for microscopic examination.

Colon Polyp Diagnosis

Polyps usually do not cause symptoms but may be detected during a colon cancer screening examination (such as flexible sigmoidoscopy or colonoscopy) or after a positive fecal occult blood test. Polyps can also be detected on a barium enema x-ray, although small polyps are more difficult to see with x-ray.

Colonoscopy is the best way to evaluate the colon because it allows the physician to see the entire lining of the colon and remove any polyps that are found. During colonoscopy, a physician inserts a very thin flexible tube with a light source and small camera into the anus. The tube is advanced through the entire length of the large intestine (colon).

The inside of the colon is a tube-like structure with a flat surface with curved folds. A polyp appears as a lump that protrudes into the inside of the colon. The tissue covering a polyp may look the same as normal colon tissue, or, there may be tissue changes ranging from subtle color changes to ulceration and bleeding. Some polyps are flat (“sessile”) and others extend out on a stalk (“pedunculated”).

Colonoscopy is also the best test for the follow-up examination of polyps. New technologies are being developed that show promise for detecting polyps (including molecular genetic tests and “virtual colonoscopy” using CT or MRI technology). Further study is needed before these tests are recommended to the general public.

Colon Polyp Removal

Polyps are removed during a colonoscopy, which means that polyps are usually removed when they are found on colonoscopy, which eliminates the chance for that polyp to become cancerous.

Procedure

The medical term for removing polyps is polypectomy. Most polypectomies can be performed through a colonoscope. Small polyps can be removed with an instrument that is tissue Larger polyps are usually removed by placing a noose, or snare, around the polyp base and burning through it with electric cautery. The cautery also helps to stop bleeding after the polyp is removed.

Polyp removal is not painful because the lining of the colon does not have the ability to feel pain. In addition, a sedative medication is given before the colonoscopy to prevent pain caused by stretching of the colon. Rarely, a polyp will be too large to remove during colonoscopy, which means that a surgical procedure will be needed at a later time.

Complications

Polypectomy is safe although it has a few potential risks and complications. The most common complications are bleeding and perforation (creating a hole in the colon). Fortunately, this occurs infrequently (one in 1000 patients having colonoscopy). Bleeding can usually be controlled during colonoscopy by cautering (applying heat) to the bleeding site; surgery is sometimes required for perforation.

After polyp removal

Medications that can increase bleeding, including aspirin, ibuprofen (Advil®, Motrin®), and naproxen (Aleve®), should be avoided for two weeks after polypectomy. Acetaminophen (Tylenol®) is safe to take. People who require anticoagulant medications such as warfarin (Coumadin®) should discuss how and when to resume this medication with their clinician.

A follow-up appointment or phone call is usually scheduled after the polyp removal to discuss the results of the tissue analysis and the need for a repeat examination.

Colon Polyp Prevention

Follow up examination — People with adenomatous polyps have an increased risk of developing more polyps, which are likely to be adenomatous. There is a 25 to 30 percent chance that adenomas will be present on a repeat colonoscopy done every three years after the initial polypectomy. Some of these polyps that adenomas will be present on a repeat colonoscopy done three years after the initial polypectomy. Some of these polyps
may have been present during the original examination, but were too small to detect. Other new polyps may also have developed.

After polyps are removed, repeat colonoscopy is recommended, usually three to five years after the initial colonoscopy. However, this time interval depends upon several factors:

- Microscopic characteristics of the polyp
- Number and size of the polyps
- A bowel preparation is needed before colonoscopy to remove all traces of feces (stool). If the bowel prep was not completed, feces may remain in the colon, making it more difficult to see small to moderate size polyps. In this situation, follow up colonoscopy may be recommended sooner than three to five years later.

Persons who undergo screening (and re-screening) for colon cancer are much less likely to die from colon cancer. Thus, following screening guidelines is one of the most important

Preventing colon cancer

Intensive research is underway to develop ways to prevent polyps and colon cancer with diet or medications. A number of nutrients and medications have been identified that may reduce the risk of colon cancer. Guidelines issued by one of the major medical societies in the United States (the American College of Gastroenterology) suggest the following to prevent polyps from recurring:

- Eat a diet that is low in fat and high in fruits, vegetables, and fiber
- Maintain a normal body weight
- Avoid smoking and excessive alcohol use

Implications For The Family

First-degree relatives (a parent, brother, sister, or child) of a person who has been diagnosed with an adenomatous polyp (or colorectal cancer) before the age of 60 years have an increased risk of developing adenomatous polyps and colorectal cancer compared to the general population. Thus, family should be made aware if the person is diagnosed with an adenoma or everyone (typically beginning at age 50), those at increased risk should begin screening earlier, typically at age 40. The best test for screening in people with an increased risk of cancer is not known, although a sensitive test (such as colonoscopy) is

Relatives can be told the following:

- People who have one first-degree relative (parent, brother, sister, or child) with colorectal cancer or an adenomatous polyp at a young age (before the age of 60 years), or two first-degree relatives diagnosed at any age, should begin screening for colon cancer earlier, typically at age 40, or 10 years younger than the earliest diagnosis in their family, whichever comes first.
- People who have one first-degree relative (parent, brother, sister, or child) with colorectal cancer or an adenomatous polyp at age 60 or later should begin screening at age 40. If the examination shows no polyps, it should be repeated similar to a person with an average risk of colon cancer.
- People with a second-degree relative (grandparent, aunt, or uncle) or third-degree relative (great-grandparent or cousin) with colorectal cancer should be screened for colon cancer similar to a person with an average risk.
